Supplemental Fig. S1. Surgical outcomes in patients with unilateral primary aldosteronism. *Complete clinical success was defined as normal blood pressure without use of antihypertensive medication; †Partial clinical success was defined as same blood pressure as before surgery with reduced number of drugs or lower blood pressure with either the same or reduced number of drugs; ‡Absent clinical success indicates unchanged or increased blood pressure with either the same or increased number of drugs; §Biochemical success was considered complete if hypokalemia and aldosterone-to-renin ratio (ARR) were normalized; ¶Partial success indicates correction of hypokalemia and a raised ARR with ≥50% decrease in baseline plasma aldosterone concentration; ‖Absent success indicates persistent hypokalemia, or persistently raised ARR, or both.
